CSE 216 Project Manager Report: Phase 5, Team Lyle

List your team members, providing name, email, and role for this project. Also provide the URL where your live Heroku-hosted web front-end can be found.

Kelli Frank as Admin, Tamara Johnson as Project Manager, Emily Weston as Web, Lizzie Shaffran as Backend, Sunny Berrios as Android.

Back-End Server

Describe the mechanism you are using to interact with Google Drive. Are you using an existing library? Are you using a REST API? Are you using some other mechanism? Were you able to get the service account to work correctly?

Unsure because it mostly isn't functional. Otherwise set up the service account but had problems interacting with google drive and setting everything up correctly.

Explain how you are using memcachier to cache documents.

It took me a while but I kind of figured out how to use a memcachier but could not cache documents since I was having problems accessing them.

Is the back-end code appropriately organized into files / classes / packages?

Yes.

Are the dependencies in the pom.xml file appropriate? Were there any unexpected dependencies added to the program?

Yes they are appropriate. Nothing unexpected but we did have to add a couple things. (memcachier)

What was the biggest issue that came up in code review of the back-end server?

Could not figure out how to upload links and files. Another issue is that it is not deploying correctly since last phase. We tried going back to previous commits but still could not find where it stopped working.

What technical debt do you see in the current back-end server implementation?

Memcachier is not implemented properly and cannot add files. also still need to fix how it is not deploying properly, but not sure what to do about that.

Describe any refactoring that was performed to reduce technical debt from the last phase

Commented out code that was not working. The code did not compile at the beginning of this phase so I had to fix that too.

Web Front-End

Describe your solution for file upload.

Used a put route to upload the file to the message after the message had already been posted.

Describe your solution for accessing images, documents, and links.

Links-used a string and made it a button that linked to the url the string represented. Images, documents-same as messages, was not able to test.

Is the web front-end appropriately organized into files / classes / packages?

Yes

Are the dependencies in the package.json file appropriate? Were there any unexpected dependencies added to the program?

Yes, had to add a jquery and bootstrap dependency in order to allow modals to function correctly.

What was the biggest issue that came up in code review of the web front-end?

Couldn't test things, lots of print statements for debugging but still kind of difficult to follow the code.

What technical debt do you see in the current web front-end implementation?

Still not caught up, and some of the code from this phase could not be tested.

Android App

Which approach to the Camera API did you use, and how well did it work?

I tried to follow the guidelines on the android developer website about Camera APIs. I'm not sure how well it worked since I cant sign in to use our app.

Describe your solution for accessing images, documents, and links.

I believe the android developer tutorial that I was using made it so that images were saved to the android's SD card, so they can be accessed through there.

Is the android app appropriately organized into files / classes / packages?

I think so.

Are the dependencies in the build.gradle file appropriate? Were there any unexpected dependencies added to the program?

The dependencies are appropriate.

What was the biggest issue that came up in code review of the android app?

Not being able to figure out the login issue. I noticed someone posted a question with a similar issue on Piazza and tried to follow those steps but was unable to solve the issue. We didn't have the "debug.keystore file" that was spoken about so I looked up how to get my SHA-256 key, but was confused as to where in the google-services.json I was supposed to update it.

What technical debt do you see in the current android app implementation?

Once we figure out the login issue and see how the Camera API was actually set up, it could not work so we would have to fix that later.

Admin Developer

Describe your policy for deciding when to delete files.

It's a judgement call depending on the admin and/or the purpose of the app.

What other roles did the admin developer play in helping the project to move forward toward completion?

I made it so that the tables work together more seamlessly. It now checks that there is overlap between the user table and the others, as well as the message table with votes and comments. I made it possible to delete posts even when they are accessed/referenced from other tables. It now deletes that info from all the respective tables.

Project-Wide

Were there any team issues that arose?

I believe communication is our biggest issue along with technical debt from other phases.

How did the amount of time your teammates spent compare to the amount of time you thought the tasks would take?

We all knew we had significant amounts of work to do over this past week and I believe most of them spent an ample amount of time on their respective pieces but I do not think we accounted for readjusting to what software we were using as well as understanding/fixing debt from last phase.

Describe the most significant obstacle or difficulty your team faced.

I would say definitely fixing debt from previous phases put the biggest dent in our time spent on understanding and working on our own tasks.

What is your biggest concern as you think ahead to the next phase of the project?

I hope we will be able to minimally fix technical debt from before and then try to implement our app plan made in class since it was a good idea.
